Radical alkyl intermediates are stabilized by similar physical processes to carbocations: as a general rule, the more substituted the radical center is, the more stable it is. This directs their reactions. Thus, formation of a tertiary radical ( $R_3C\cdot$ ) is favored over secondary ( $R_2HC\cdot$ ), which is favored over primary ( $RH_2C\cdot$ ). Likewise, radicals next to functional groups such as carbonyl, nitrile, and ether are more stable than tertiary alkyl radicals.

Hydroxyl radicals are highly reactive species that attack most of the organic molecules. They are highly oxidizing in nature which is attributed to their oxidation potential (Tchobanoglous et al., 2003). In addition, owing to their nonselective nature, many susceptible organic molecules can easily be removed or degraded using hydroxyl radical (e.g., acids, alcohols, aldehyde, aromatics, amines ...
